What is Software Defined Radio?

A [soft radio](#) samples RF and performs modulation, mixing and conversion using digital software rather than analog hardware.

Sampling:

Recording a continuous analog waveform as a set of discrete digital measurements.

Nyquist:

Sample more often than twice the frequency of the signal to reconstruct it. If you don't, an alias will appear.

Oscillator:

A functional block that generates a single frequency. The wave form can be sinusoidal or square.

Output

Output

“Oscillators amplify
and
amplifiers oscillate.”

Generalized Filter:

A functional block that performs signal processing.

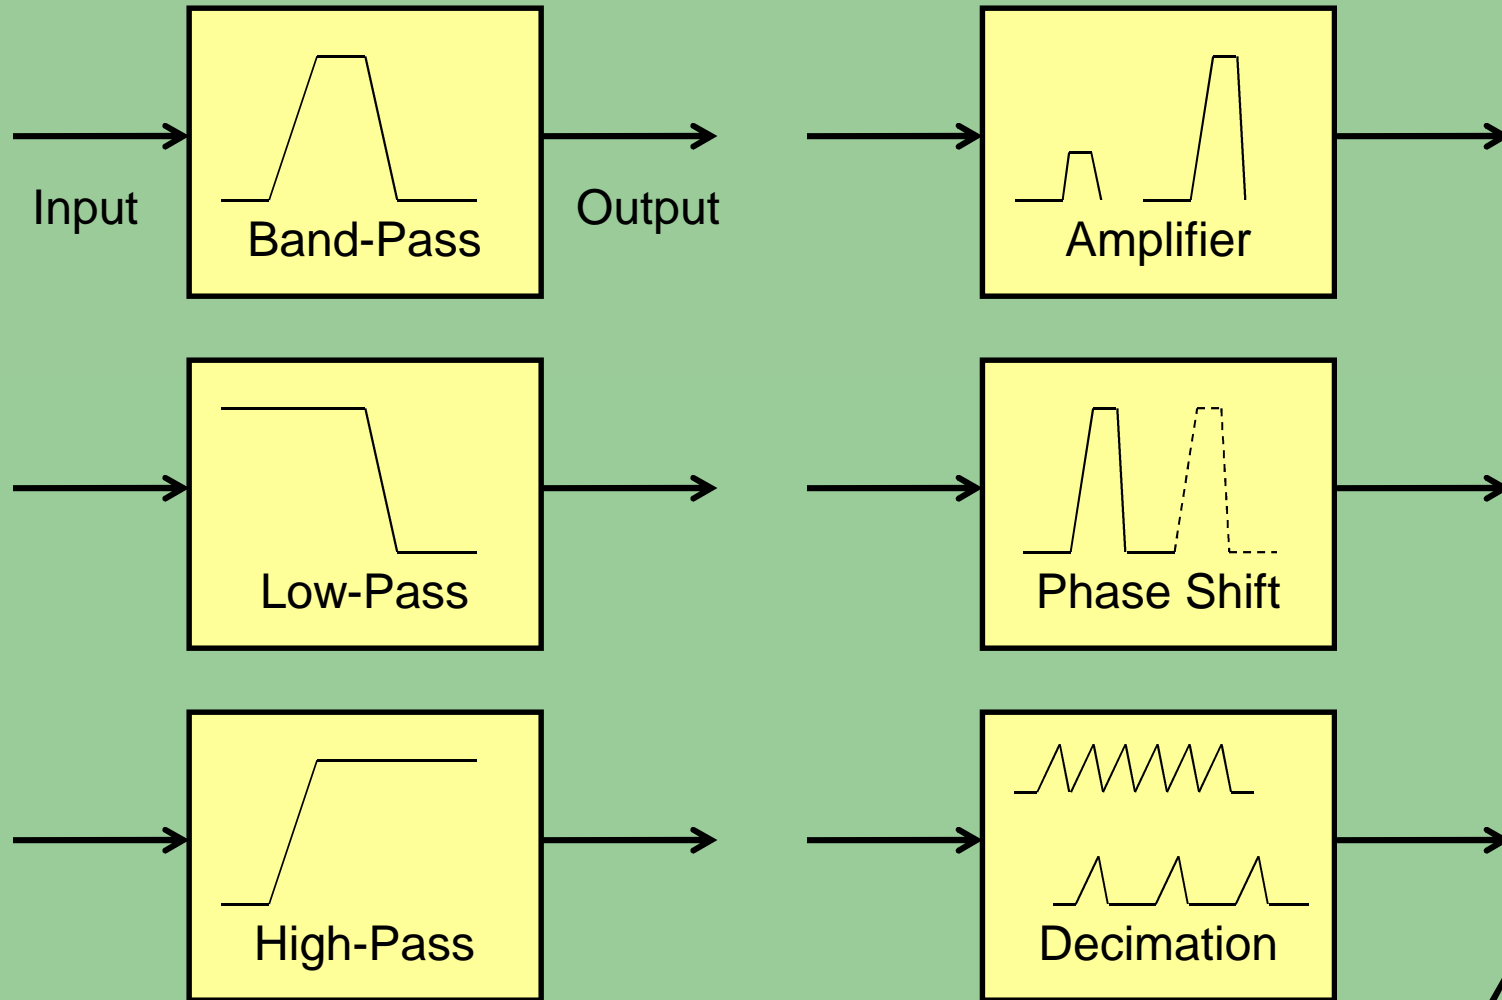

A filter may be analog or digital.

A filter may operate in time or frequency domain.

“Filters amplify
and
amplifiers filter.”

Filter Examples:

Mixer:

An Audio mixer sums two signals.

An RF mixer multiplies two signals.

The results are not the same!

Audio Mixer:

An Audio mixer adds two signals, creating a superposition of the original:

RF Mixer:

An RF mixer multiplies two signals creating two completely new signals at stations $A - B$ and $A + B$.

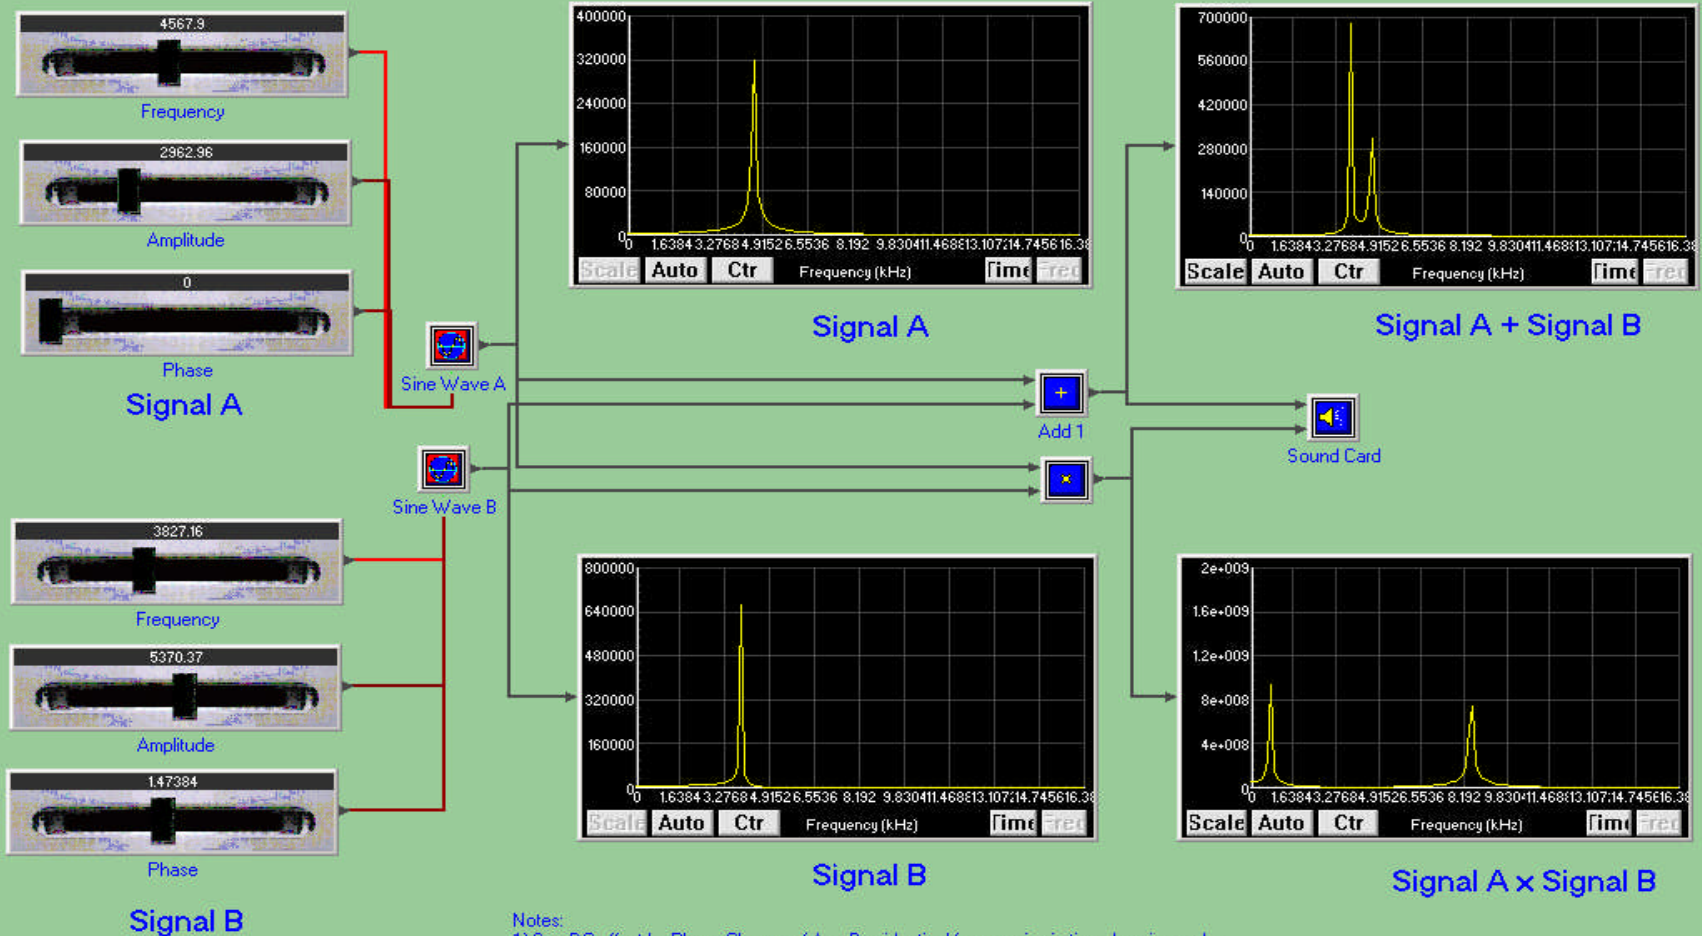

Mixer:

When referring to RF the term
product mixer
may reduce confusion.

Blazing Fast SDR:

Principles

Mixer Demonstration

Detector/Demodulator:

Separates the original signal from the RF carrier on which it was modulated.

ADC: Analog to Digital Converter

Samples a continuous analog signal and converts it to a set of digital numbers:

ADC: Signal Exists in World

ADC: Given As Voltage over Time

ADC: Choose sampling frequency.

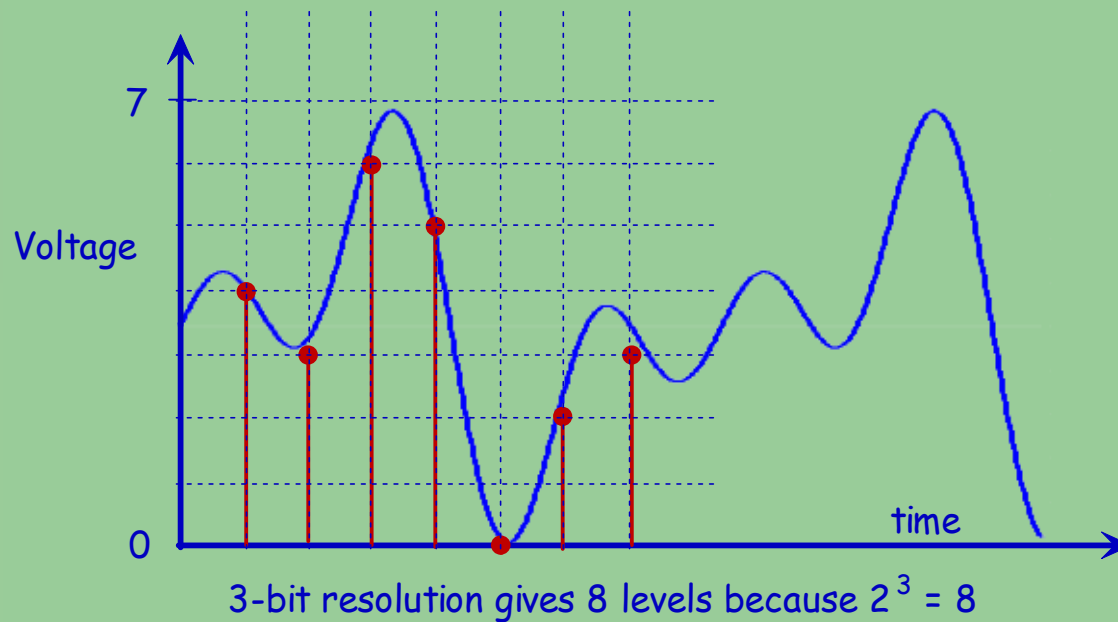

ADC: Choose number of voltage levels.

3-bit resolution gives 8 levels because $2^3 = 8$

ADC: Sample signal to nearest level.

ADC: a small error occurs.

ADC: “quantization” error.
